

# MboaTrust AI

## UI/UX Specification and Design Review Aligned to the current merchant mobile UI screens

### Document purpose

Replace the earlier generic specification with a screen-aligned UI/UX document that reflects the actual merchant app design now available.

### Version

2.0 — updated after review of the provided UI screens

### What this revised document now does

- Uses the provided UI screens as the primary reference for the merchant mobile experience.
- Captures what is already strong in the current design, where friction remains, and what should be improved before development or high-fidelity prototype sign-off.
- Keeps the merchant-first direction of MboaTrust AI: quick payment verification, simple records, visible trust building, and low-friction daily use.

## 1. Executive assessment

The current MboaTrust AI merchant interface is already strong in brand consistency, trust signaling, and product relevance. The green-led palette, rounded card system, clear result states, and supportive informational pages make the app feel calmer and more credible than a generic fintech prototype. The design also reflects the right product priorities: verification, business record keeping, AI insights, and trust score growth.

The next round of improvement should focus less on visual reinvention and more on refinement. Several screens still carry small secondary text, dense stacked cards, and uneven information hierarchy. Tightening typography, spacing, status logic, and state behavior will make the product easier for real merchants to understand in a busy market environment.

| What already works well                                               | Why it matters                                                                                             |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Consistent trust-centered branding across all screens                 | The product immediately feels like one coherent system, which is critical for a payment-verification tool. |
| Clear status outcomes for suspicious, pending, and confirmed payments | Merchants can quickly understand the risk state and decide whether to release goods.                       |
| Good coverage of help, privacy, offline, empty, and success states    | This improves confidence and shows the product is designed for real use, not only demo flows.              |
| Strong task coverage in records and summary screens                   | The app goes beyond verification and becomes a daily business utility, increasing repeat usage.            |

| Main improvement areas                                               | Recommended direction                                                                                    |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Secondary text and chart labels are sometimes too light or too small | Raise baseline body contrast, increase small-label size, and reserve tiny text for captions only.        |
| Some screens stack too many cards before the primary action          | Reduce scroll friction by trimming explanatory copy and promoting the key CTA or value above the fold.   |
| Form screens vary in visual density                                  | Standardize label placement, helper text, error treatment, field height, and button spacing.             |
| A few informational pages feel dense for low-tech users              | Simplify by chunking content into collapsible or progressive sections with short, plain-language labels. |

## 2. Product and user alignment

The provided UI screens align well with the real usage context of MboaTrust AI: informal merchants, quick daily decisions, limited time, and a strong need for reassurance before releasing goods or logging transactions. The interface language is more human than technical, which is correct for this audience.

- Primary merchant need: verify incoming proof of payment as quickly and safely as possible.

- Secondary merchant need: log sales, expenses, and stock purchases without heavy typing.
- Longer-term product need: build a trust score and useful business record that can support future financial services.
- Operating conditions: low-end Android devices, unstable connectivity, mixed literacy levels, and bilingual usage.

### 3. Current design language based on the provided screens

The present visual language is strong enough to keep and formalize into a design system. The goal is not to redesign from zero, but to lock down the system so future screens remain consistent.

| Design element | Current direction seen in the UI                                                           | Refined specification to use going forward                                                                 |
|----------------|--------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Color          | Emerald green primary, pale mint surfaces, soft neutrals, amber for caution, red for risk. | Keep the palette. Formalize it into tokens and use red sparingly so risk screens stay meaningful.          |
| Typography     | Rounded, friendly heading style with soft body text.                                       | Use a clear type scale: 28–32 for hero numbers, 20–24 for page titles, 15–16 for body, 12–13 for metadata. |
| Cards          | Rounded cards with gentle shadows and generous vertical stacking.                          | Keep rounded cards, but reduce card count on dense pages and standardize padding.                          |
| Buttons        | Wide pill buttons and calm secondary actions.                                              | Primary CTAs should stay full-width on key flows. Secondary actions should remain visible but quieter.     |
| Navigation     | Five-tab bottom navigation used consistently.                                              | Keep the five-tab structure and enforce icon + label clarity with accessible selected states.              |

#### Recommended token palette aligned to the current UI

- Primary emerald: #0B7864
- Secondary mint surface: #F3F7F3
- Text primary: #1F2D27
- Text secondary: #66746F
- Border / divider sage: #D9E7DF
- Warning amber: #F4B23E
- Risk coral-red: #E56C64
- Success confirmation green: use a deeper emerald rather than a separate neon green

### 4. Information architecture and navigation

The current app structure is easy to understand and already reflects a sensible merchant workflow. The five-tab bottom navigation supports the right mental model: a merchant opens the app, verifies a payment, records activity, checks insights, and manages profile settings.

- Home: keep today's sales, trust score, recent activity, and one prominent verification shortcut.
- Verify: keep this as the operational core for upload, camera capture, manual entry, pending results, and verification history.
- Records: focus on fast entry for sales, expenses, and stock plus simple searchable history.
- Insights: show only the most useful metrics above the fold; avoid making the page feel over-analytical.
- Profile: group identity, alerts, language, permissions, and support into clean, clearly separated sections.

### 5. Screen-by-screen specification and improvement notes

The tables below turn the observed screens into an actionable specification. Each module lists the current screens, the main UX purpose, and the recommended refinements for the next design pass.

## 5.1 Entry, onboarding, and access

| Observed screen       | Purpose                                     | What is already working                                    | What to improve next                                                                         |
|-----------------------|---------------------------------------------|------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Splash screen         | Instant brand recognition and loading state | Strong premium feel, clean brand-first moment.             | Add a subtle progress cue or micro-copy only if loading exceeds a second.                    |
| Welcome / landing     | Explain value and encourage first action    | Human image and value proposition create warmth and trust. | Increase contrast of secondary text and reduce the first screen's text block slightly.       |
| Login                 | Fast returning-user access                  | Simple and focused. Strong CTA.                            | Raise placeholder contrast and make error states more explicit.                              |
| Forgot password       | Recovery without support dependency         | Calm layout and consistent form style.                     | Show expected SMS timing and failure fallback clearly.                                       |
| OTP / Verify identity | Confirm ownership of phone number           | Clear 6-digit flow and strong primary action.              | Make resend logic clearer and add a visible edit-number action.                              |
| Merchant registration | New user onboarding                         | Relevant fields and consent visibility.                    | Break into two short steps on smaller devices to reduce fatigue.                             |
| Language selection    | Choose user language early                  | Clean and easy to scan.                                    | Mark current selection more strongly and show that language can be changed later in Profile. |

## 5.2 Home, support, profile, and trust pages

| Observed screen      | Purpose                          | Keep                                                                            | Improve                                                                                |
|----------------------|----------------------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Homepage             | Daily operational dashboard      | The sales total, trust score, and quick actions are appropriate and motivating. | Reduce below-the-fold density and keep one dominant CTA such as Check Payment.         |
| Notifications        | Risk alerts and system updates   | Cards use severity well and feel actionable.                                    | Increase spacing between stacked alert blocks and make timestamps easier to scan.      |
| Help & Tutorial      | Self-service guidance            | Good support tone and reassuring visuals.                                       | Group content into categories such as Verification, Trust Score, Records, and Support. |
| Privacy & Consent    | Build trust through transparency | Very strong tone and structure.                                                 | Add a short one-line consequence under each permission toggle.                         |
| AI Insights & Alerts | Translate analysis into action   | Useful card pattern and good status variety.                                    | Tighten copy length and make tertiary labels more legible.                             |
| Offline mode status  | Guide use when internet is down  | Excellent real-world scenario coverage.                                         | Add last sync time, queued action count, and a retry action.                           |

| Observed screen              | Purpose                                           | Keep                                                | Improve                                                                                |
|------------------------------|---------------------------------------------------|-----------------------------------------------------|----------------------------------------------------------------------------------------|
| Empty state — history        | Guide first-time behavior                         | Friendly and clear.                                 | Add a small example of the first action a merchant should take.                        |
| Profile & Settings           | Identity, preferences, and settings               | Good information coverage.                          | Break into sections or accordions so it feels less dense.                              |
| Merchant trust score details | Show score, status, and growth path               | Very compelling and differentiated.                 | Add a short explanation of score update frequency and timeframe.                       |
| Trust score onboarding       | Introduce trust-building value after verification | Good bridge from verification to longer-term value. | Show 2–3 concrete drivers of the score on this screen or the next.                     |
| Sales history                | Review recorded sales                             | Search and filter are correctly prioritized.        | Improve row readability with stronger metadata alignment and payment method filtering. |

## 5.3 Payment verification module

| Observed screen          | Purpose                                        | Keep                                                      | Improve                                                                           |
|--------------------------|------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------------------------------------------|
| Verification onboarding  | Explain value before first use                 | Good merchant education and trust framing.                | Shorten copy so the CTA appears even earlier on smaller screens.                  |
| Verification hub         | Central entry to verification actions          | Strong module identity and clear options.                 | Promote the most-used action based on analytics once live.                        |
| Upload / capture payment | Collect the payment evidence                   | Camera and gallery actions are clear.                     | Add small image-quality tips directly above the CTA and clarify permissions.      |
| Manual payment entry     | Fallback when screenshot upload is unavailable | Very practical for real merchants.                        | Use numeric keyboard defaults and optional network / sender presets.              |
| Result — pending         | Show that the system needs more time           | Useful reassurance and clean layout.                      | Display expected wait duration and a notify-me / check-again option.              |
| Result — suspicious      | Warn the merchant not to release goods         | Strong visual severity and helpful risk-factor structure. | Add a short action checklist: hold goods, review amount, request alternate proof. |
| Result — looks confirmed | Show a positive but measured outcome           | Excellent high-confidence success state.                  | Keep wording cautious: 'looks confirmed' is better than absolute certainty.       |

## 5.4 Records, finance, and business health module

| Observed screen          | Purpose                          | Keep                                                              | Improve                                                                        |
|--------------------------|----------------------------------|-------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Success — record saved   | Acknowledge successful logging   | Clean, satisfying finish state.                                   | Allow the screen to auto-close after a short delay, with manual override.      |
| Add sale                 | Fast sale capture                | Numeric keypad and payment method toggle are excellent for speed. | Add smart defaults and optional recent item suggestions.                       |
| Add expense              | Track outgoing cash              | Chip-based categories are easy to tap.                            | Use stronger field labels and a numeric keypad for amount by default.          |
| Add stock purchase       | Record business restocking       | Relevant fields and useful category chips.                        | Trim the AI assistant copy so the form itself remains dominant.                |
| Track records onboarding | Explain why logging matters      | Good positioning of records as profit-building behavior.          | Shorten copy slightly and keep the first real action closer to the fold.       |
| Financial summary        | Show business health at a glance | The summary card structure is strong.                             | Increase chart-label legibility and expose the chosen date range more clearly. |

## 6. Core interaction and state specification

The current UI already shows a mature set of states. The specification below formalizes how those states should behave in the design system and later in development.

| State             | Use it on                                               | Required behavior                                                                                      |
|-------------------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Loading           | Verification processing, dashboard fetch, history fetch | Use skeletons or calm progress indicators; never leave a blank screen that looks broken.               |
| Success           | Saved records, verified actions, settings updates       | Show a short confirmation, preserve user context, and provide one next action.                         |
| Warning / Pending | Verification awaiting confirmation, incomplete forms    | Use amber tone plus explanation text and a clear next step.                                            |
| Risk / Suspicious | High-risk verification result                           | Use red only for high-importance alerts, with action guidance and non-alarmist wording.                |
| Empty             | New users, empty history, no insights yet               | Use instructional empty states that explain the benefit of the first action.                           |
| Offline           | No connection or queued sync                            | Let the merchant continue where safe, show what will sync later, and surface retry / last sync status. |
| Error             | Form validation, upload failure, auth failure           | Use inline error messages near the field or action, not only a toast.                                  |

## 7. Design refinements to prioritize next

This section translates the review into concrete design changes that will improve usability without disrupting the current visual identity.

| Priority | Refinement                                                                    | Expected impact                                                                     |
|----------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| P0       | Raise body and helper-text contrast across all screens.                       | Immediate readability improvement, especially for busy merchants and older devices. |
| P0       | Standardize form field heights, helper text, and validation treatment.        | Less friction and fewer mistakes during registration and record entry.              |
| P0       | Reduce card stacking on dense screens such as Home, Profile, and Help.        | Faster scanning and less fatigue.                                                   |
| P1       | Improve chart and mini-graph readability in Insights and Summary.             | Metrics become more useful instead of decorative.                                   |
| P1       | Add explicit next-step language to suspicious and pending results.            | Merchants know exactly what to do after each outcome.                               |
| P1       | Introduce section grouping or accordion structure in Profile and Settings.    | Improves manageability without losing feature coverage.                             |
| P2       | Add subtle achievement and progress cues tied to trust score growth.          | Encourages repeat use without turning the product into a game.                      |
| P2       | Add optional quick-entry automation such as recent items or saved categories. | Speeds up repeated records for daily merchants.                                     |

### Microcopy guidance to preserve the current tone

- Keep action labels short: Check Payment, Save Sale, Save Expense, View Advice, Learn How It Works.
- Use cautious success wording: 'Looks confirmed' or 'Matches our records' rather than absolute certainty.
- Use plain-language risk reasons: amount mismatch, low image quality, missing details, unrecognized pattern.
- Make support language human and non-technical: 'Need help? Contact support' beats jargon-heavy AI explanations.

## 8. Accessibility and localization notes

- Minimum body text should remain comfortably readable; avoid depending on 11–12 px equivalents except for captions.
- Do not rely on color alone. Every risk, pending, or confirmed state must also use text and iconography.
- English and French must be checked screen by screen for overflow, especially in buttons, chips, and settings labels.
- Ensure tap targets remain large enough on chips, filters, bottom navigation, and verification actions.
- Use high-contrast focus and selected states for keyboard, QA, and accessibility support.

## 9. Frontend handoff notes

The current design is ready to be translated into a component-driven frontend specification. Development should not recreate screen-by-screen styling manually; instead, the UI should be built from reusable tokens and components extracted from the current design language.

- Create design tokens for color, typography, spacing, radii, shadow, status fills, and icon sizes.
- Componentize the following first: app bars, full-width buttons, metric cards, trust score cards, status result panels, list rows, form fields, category chips, filter bars, and bottom navigation.
- Record each state for each critical component: default, pressed, focused, disabled, loading, error, success.
- Capture responsive behavior for very short devices so the most important CTA remains visible without excessive scrolling.
- Treat the current merchant mobile app as the primary production path. The admin dashboard should be specified separately if not already designed.

## 10. Updated acceptance checklist

| Acceptance question                                                            | Pass condition                                                                                               |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Can a first-time merchant understand the product within the first 2–3 screens? | Welcome, onboarding, and registration explain value in plain language with one clear primary action.         |
| Is the Verify workflow obvious and safe?                                       | Verification hub, capture/manual flows, and result states clearly guide the merchant toward the next action. |
| Can merchants record daily activity quickly?                                   | Add Sale, Add Expense, and Add Stock Purchase screens are                                                    |

|                                                                       |                                                                                                |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
|                                                                       | operable in seconds with minimal typing.                                                       |
| Is trust built through the UI itself?                                 | Privacy, help, consent, support, and trust score explanations feel transparent and reassuring. |
| Are empty, offline, loading, and error states covered?                | Each core module includes explicit UI behavior for these cases.                                |
| Can the interface survive translation and low-end device constraints? | Typography, spacing, and button widths remain readable in both English and French.             |

## 11. Recommended next design package

- A cleaned design-system page in Figma containing color tokens, type scale, spacing, radii, icons, buttons, fields, chips, cards, and state variants.
- A short clickable prototype for the main path: Home → Verify → Result → Save to Sales.
- French-language QA screens for at least registration, verification results, summary, and settings.
- One low-connectivity demo flow showing offline record capture and later sync recovery.
- A separate admin-dashboard specification once the merchant app is stabilized.

## Appendix A. Current UI visual inventory

The following reference sheets were used to align this document to the current merchant mobile UI. They are not a substitute for the editable Figma file, but they are sufficient to ground this revised specification in the actual screens already designed.

Figure A1. Entry, onboarding, registration, and access screens.

Figure A2. Home, notifications, help, privacy, offline, profile, history, and language screens.

Figure A3. Verification hub, capture/manual flows, and result-state screens.

Figure A4. Records, trust score details, and financial-summary screens.
